Land use impacts in product life cycles

t

project

Different situations of land use:

Occupation with equilibrium reference

Experiences of linking 2 European LCI databases and their fit for CO₂ emissions for 2000 use impacts

project

Different situations of land use:

Occupation with average reference (here with higher quality level)

Experiences of linking 2 European LCI databases and their fit for CO₂ emissions for 2000 use impacts

project

Different situations of land use:

Occupation during renaturation (with different end levels)

Experiences of linking 2 European LCI databases and their fit for 2050 use impacts

project

Different situations of land use:

Transformation (with different end levels)

Experiences of linking 2 European LCI databases and their fit for 2050 use impacts

project

Different indicators and impact factors:

Biodiversity

- local plant species diversity (SD_i)
- global ecosystem scarcity (ES_i)
- global ecosystem vulnerability (EV_i)

Ecosystem Occupation $EO = A \times t \times SD_i \times ES_i \times EV_i$

Ecosystem Transformation $ET = A \times SD_i \times ES_i \times EV_i$

(for each biome i)

Life support systems

- Net primary (biomass) productivity (NPP)

Biomass Occupation $BO = A \times t \times (f)NPP$

Biomass Transformation $BT = A \times (f)NPP$

Experiences of linking 2 European LCI databases and fit CO₂ emissions for 2001 use impacts

Experiences with the Ecoinvent 1996 database

- Mixing of occupation and transformation
- Mixing of occupation and renaturation
- Hard to find all information to determine ETH values for occupation, renaturation and transformation
- Hard to perform a dominance analysis

Experiences of linking 2 European LCI databases and fit CO₂ emissions for 2001 use impacts

Experiences with the EcoInvent 1996 database

Experiences of linking 2 European LCI databases and their use in life cycle assessment

Experiences with the EcoInvent 1996 database

Experiences of linking 2 European LCI databases and their use in life cycle assessment

Results from the EcoInvent 1996 database

Analysis of 'Strom ab Steinkohle Kraftwerk NL' type II>III

- About 70 % directly related to the following process cards:
 - 'Steinkohle aus Tagbau ab Bergwerk' 52%
 - 'Infra Schiene' 2%
 - 'Steinkohle aus Untertagebau ab Australische Bergwerk' 4%
 - 'Steinkohle aus Untertagebau ab Os Europa Bergwerk' 3%
 - 'Steinkohle aus Untertagebau ab Sud afrik Bergwerk' 3%
 - 'Steinkohle aus Untertagebau ab Nord amerik Bergwerk'

Experiences of linking 2 European LCI databases and a fit CD. Setback for 2001 use impacts

Results from the EcoInvent 1996 database

Experiences of linking 2 European LCI databases and a fit CD. Setback for 2001 use impacts

Experiences with the IVAM ER database

- Hard to include different land use data when basic databases do not offer an adequate format or no data
- Repeating the procedure for data collection from statistics with more effort results in lower uncertainty ranges and higher confidence in data
- Direct occupation figures for NL seem much lower than those of ETH

Experiences of linking 2 European LCI databases and fit CO₂ emissions for 2001 use impacts

Data collection and -treatment in TNO project

Experiences of linking 2 European LCI databases and fit CO₂ emissions for 2001 use impacts

Procedure for dealing with transformation of 'unended' land uses in TNO project

- **Determine an increasing trend** in land use for the concerning activity. Apply various time ranges to determine the variability of the trend over time. If there is no relevant or a negative trend, no transformation is attributed to that type of activity.
- Determine via land cover change statistics the **type(s) of land use before the activity** in case of a relevant trend, **and their contribution in percentage**. When there are stock-type land users (storage, barren building area, etc.) look further back to determine what was the previous user.
- **Calculate the national transformation from each previous user** in m²/y (gross transformation data are preferred over net data).
- **Determine the productivity** (e.g. in either kg/y or tkm/y) using statistics, based on the average (and last) years performance (giving a range).
- Allocate the productivity to the relevant output use in case of multi-functionality
- Divide the land transformation for each previous user separately by the (allocated) productivity of that activity, This gives the **transformation per FU**.

Experiences of linking 2 European LCI databases and their use for 2010 and 2050 impacts

Requirements of the TNO method for inventory data

- **Separate occupation and transformation**
- **Separate the renaturation part of occupation**
- **Separate interventions of emissions and land use**
- **Differentiate at least between regions in continents**

• **Distinguish 20 occupation types and about 15**

Experiences of linking 2 European LCI databases and their use for 2010 and 2050 impacts

differentiation

Experiences of linking 2 European LCI databases and eafit, C20, Setra, for 2001 use impacts

some consequences of only using the 13 land use types proposed in [Frischknecht & Koellner, 2001]

- Agriculture and forestry can not be included
- No distinction possible between impacts of organic and traditional agriculture
- No distinction possible between impacts of different types of forest
- Transformations due to water barrages can not be included

Experiences of linking 2 European LCI databases and eafit, C20, Setra, for 2001 use impacts

Conclusions

- **Land use data collection is very time consuming =>**
get land use data adequately in the EcoInvent 2000 database
- **An adequate land use format must include regional differentiation => proposed format:**
occupation ([type], [country code])
transformation ([type initial]>[type final], [country code])
- **Differentiate at least 20 different land occupation types and about 15 different transformation types**
