# Modelling Biodiversity in Fuzzy Terms

Swiss LCA Discussion Forum  
Zürich, March 15<sup>th</sup>, 2016

---

Ganzheitliche Bilanzierung

 **Fraunhofer**  
IBP

---

# Agenda

---

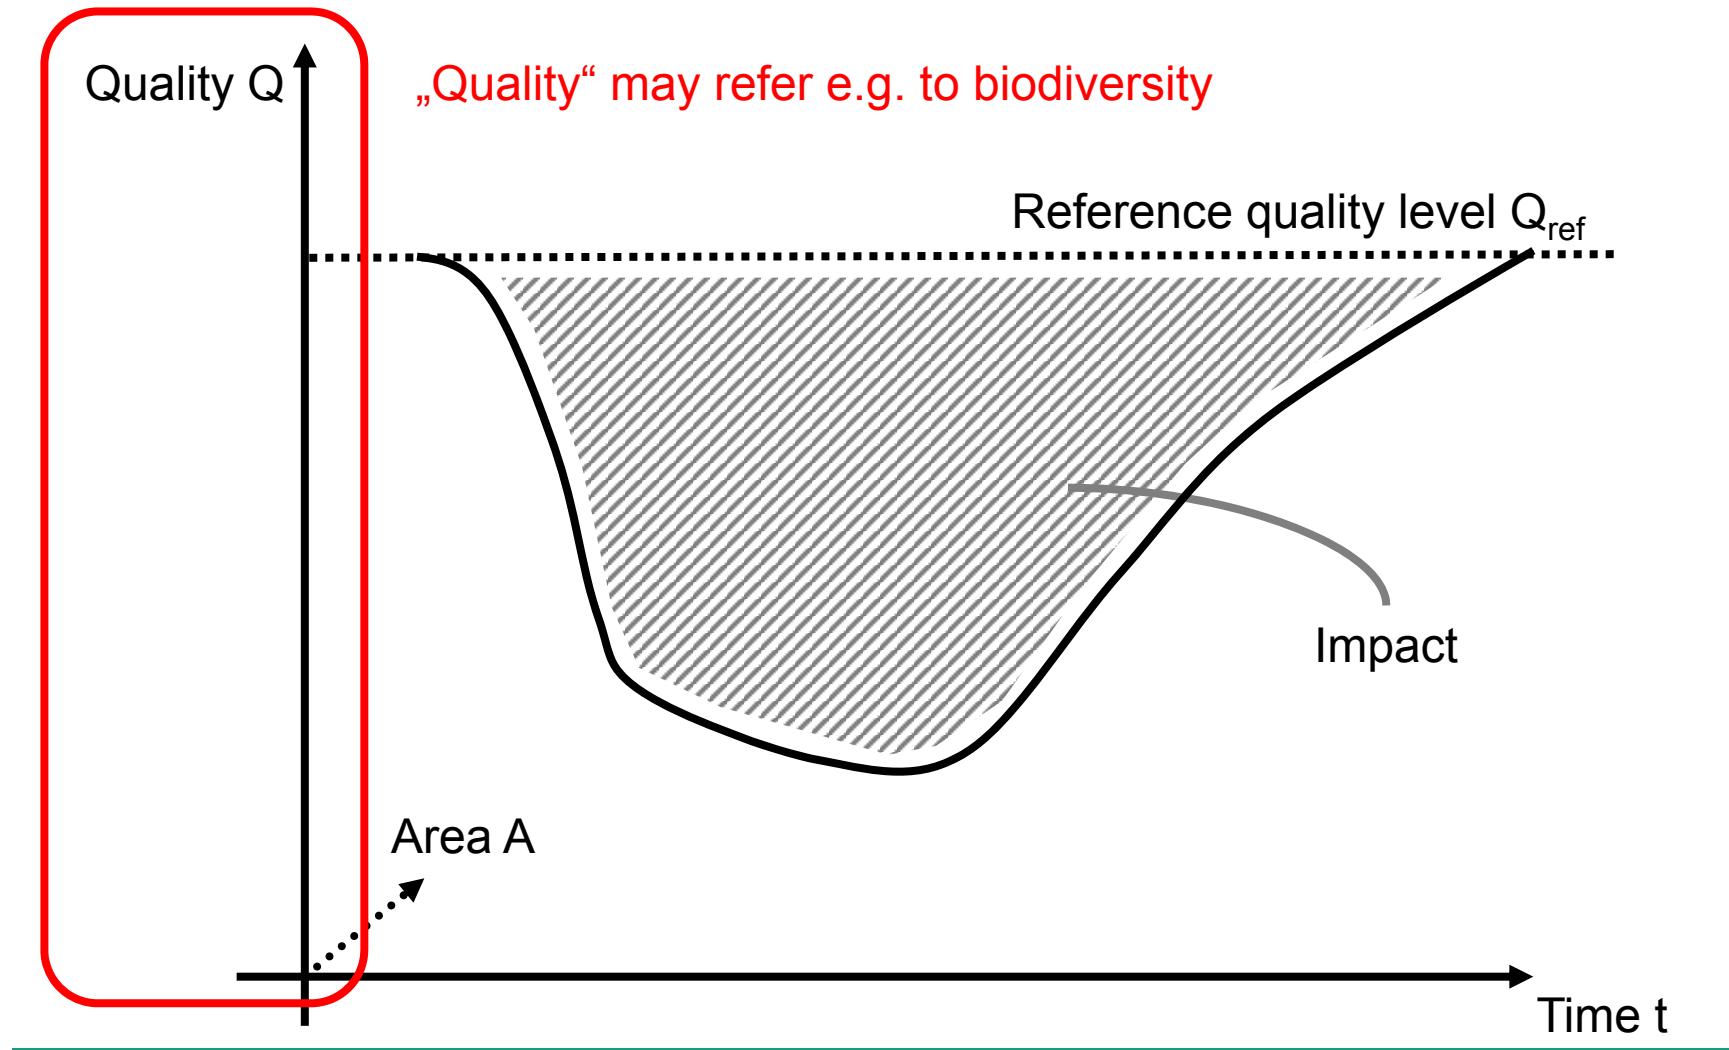

- Context: Land use in LCA
- Challenge: biodiversity as a fuzzy subject
- Biodiversity Impact Assessment
  - Assessment principle
  - Parameters and biodiversity contributions
  - Aggregation
- Conclusion/outlook/critique

Ganzheitliche Bilanzierung

# UNEP-SETAC LCI Framework for land use in LCA

Ganzheitliche Bilanzierung

Fraunhofer  
IBP

# What do we actually want to protect?

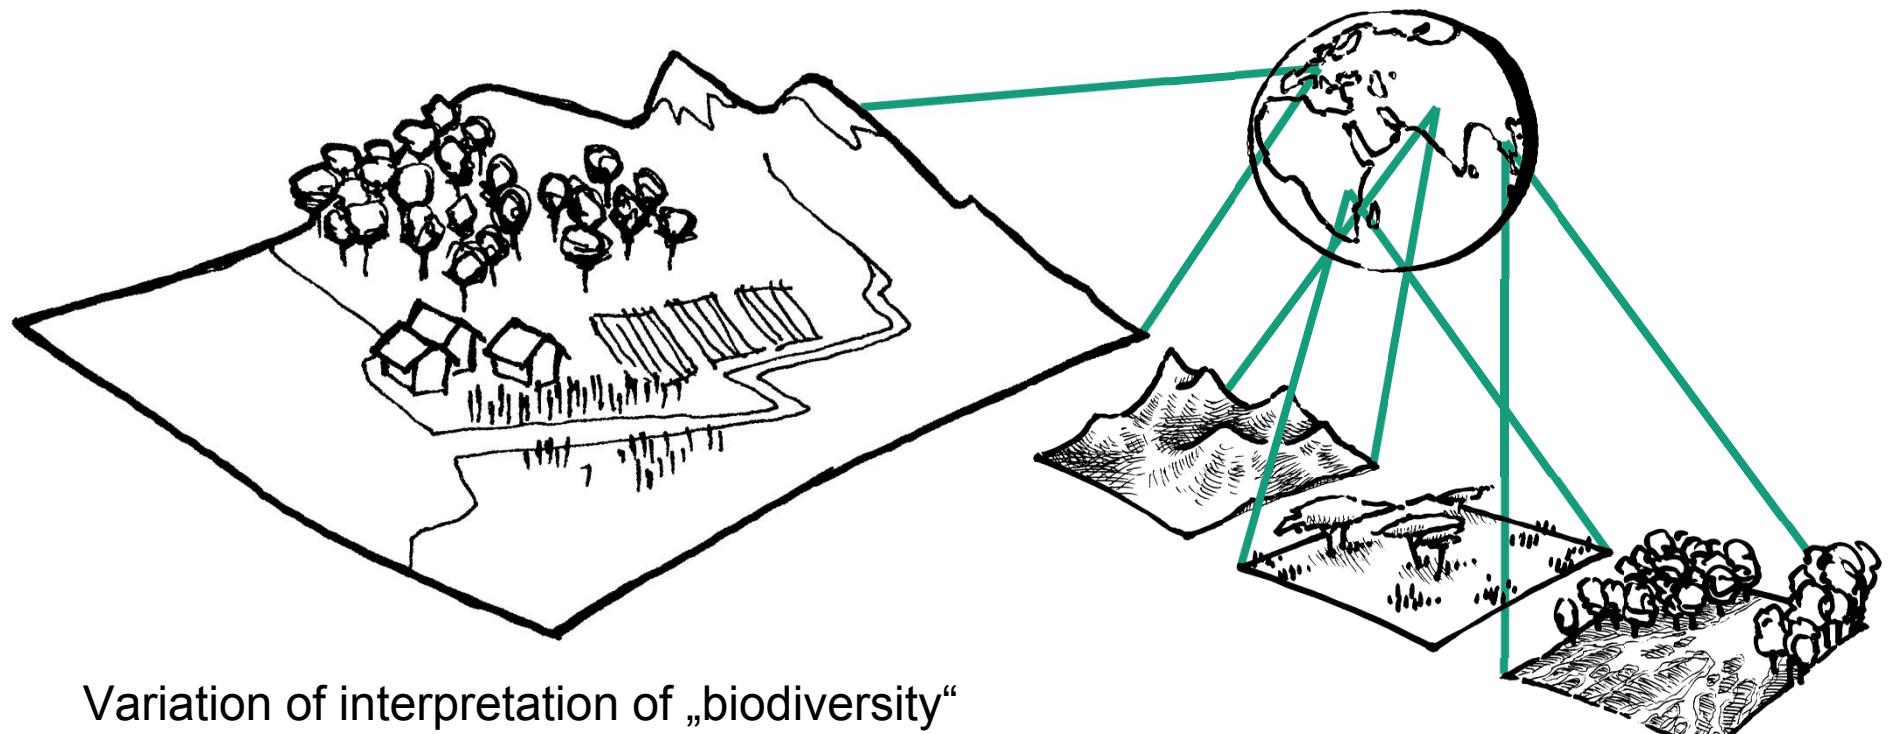

Differing interpretations of „biodiversity“

- Scientific
  - Description of defined samples  
e.g. areas, organisms
  - Based on physical reality
  - No inherent normative meaning
- Political
  - Buzzword, fuzzy/diffuse meaning
  - Refers somehow to conservation policies
  - Strong normative contents

Ganzheitliche Bilanzierung

# Regional differentiation

Variation of interpretation of „biodiversity“

- Biogeographic context
- Cultural context

# Expert involvement

Augment literature research with expert knowledge to formulate parameter relations and eventually a formal biodiversity expression

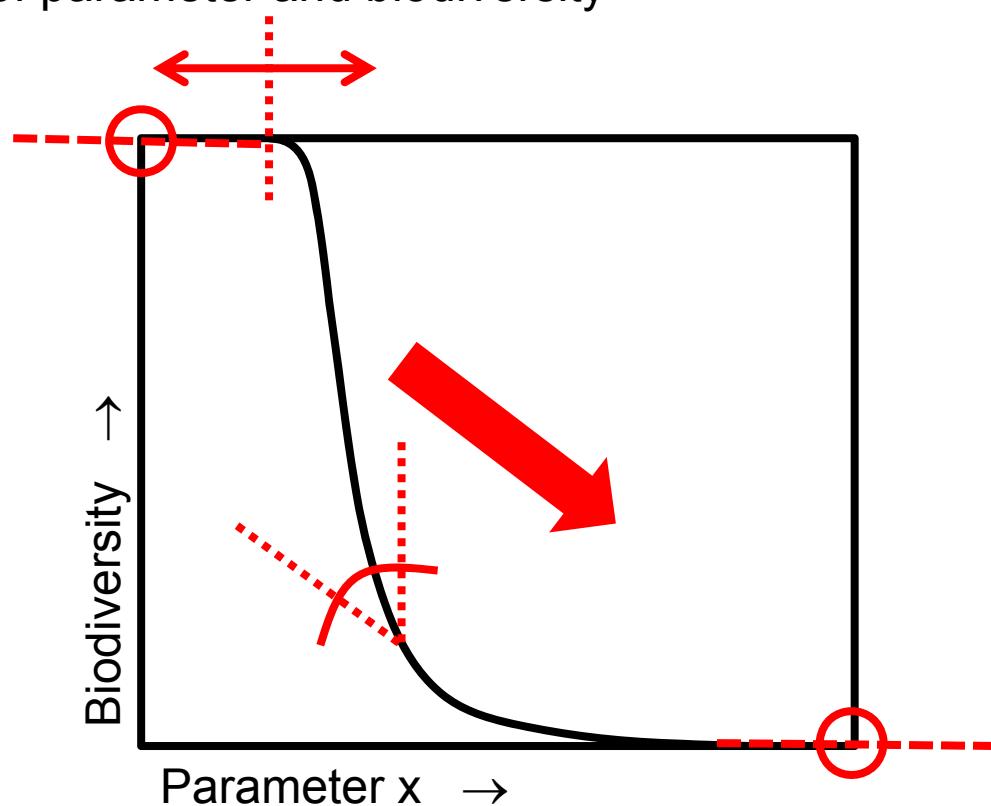

- Preparation
  - Literature research: typical biodiversity of ecoregion, break down global drivers of biodiversity loss to regional level
  - Identify set of parameters as a starting point
  - If possible, produce biodiversity contribution functions
  - Choose interview partners
- Interviews
  - Discuss parameters qualitatively, discuss relevance of parameters
  - Develop biodiversity contribution of individual parameters graphically
  - Formal expression of function, get confirmation

# Biodiversity contribution per parameter

Goal: quantitative relationship of parameter and biodiversity

- Simple, empty graph space
- General direction
- Fixed points
- Tangents
- Interpolation
- Adjustments

Ganzheitliche Bilanzierung

# Aggregation of biodiversity contributions

Aggregation of biodiversity contribution per parameter

- Contribution from each parameter in the (0, 1) range
- For independent parameters
  - Addition, equal weighting
  - If specific parameters more important, uneven weighting
- For entangled parameters
  - Limiting factors → MIN
  - Compensating effect → MAX
  - More complex relations → other mathematical expressions available

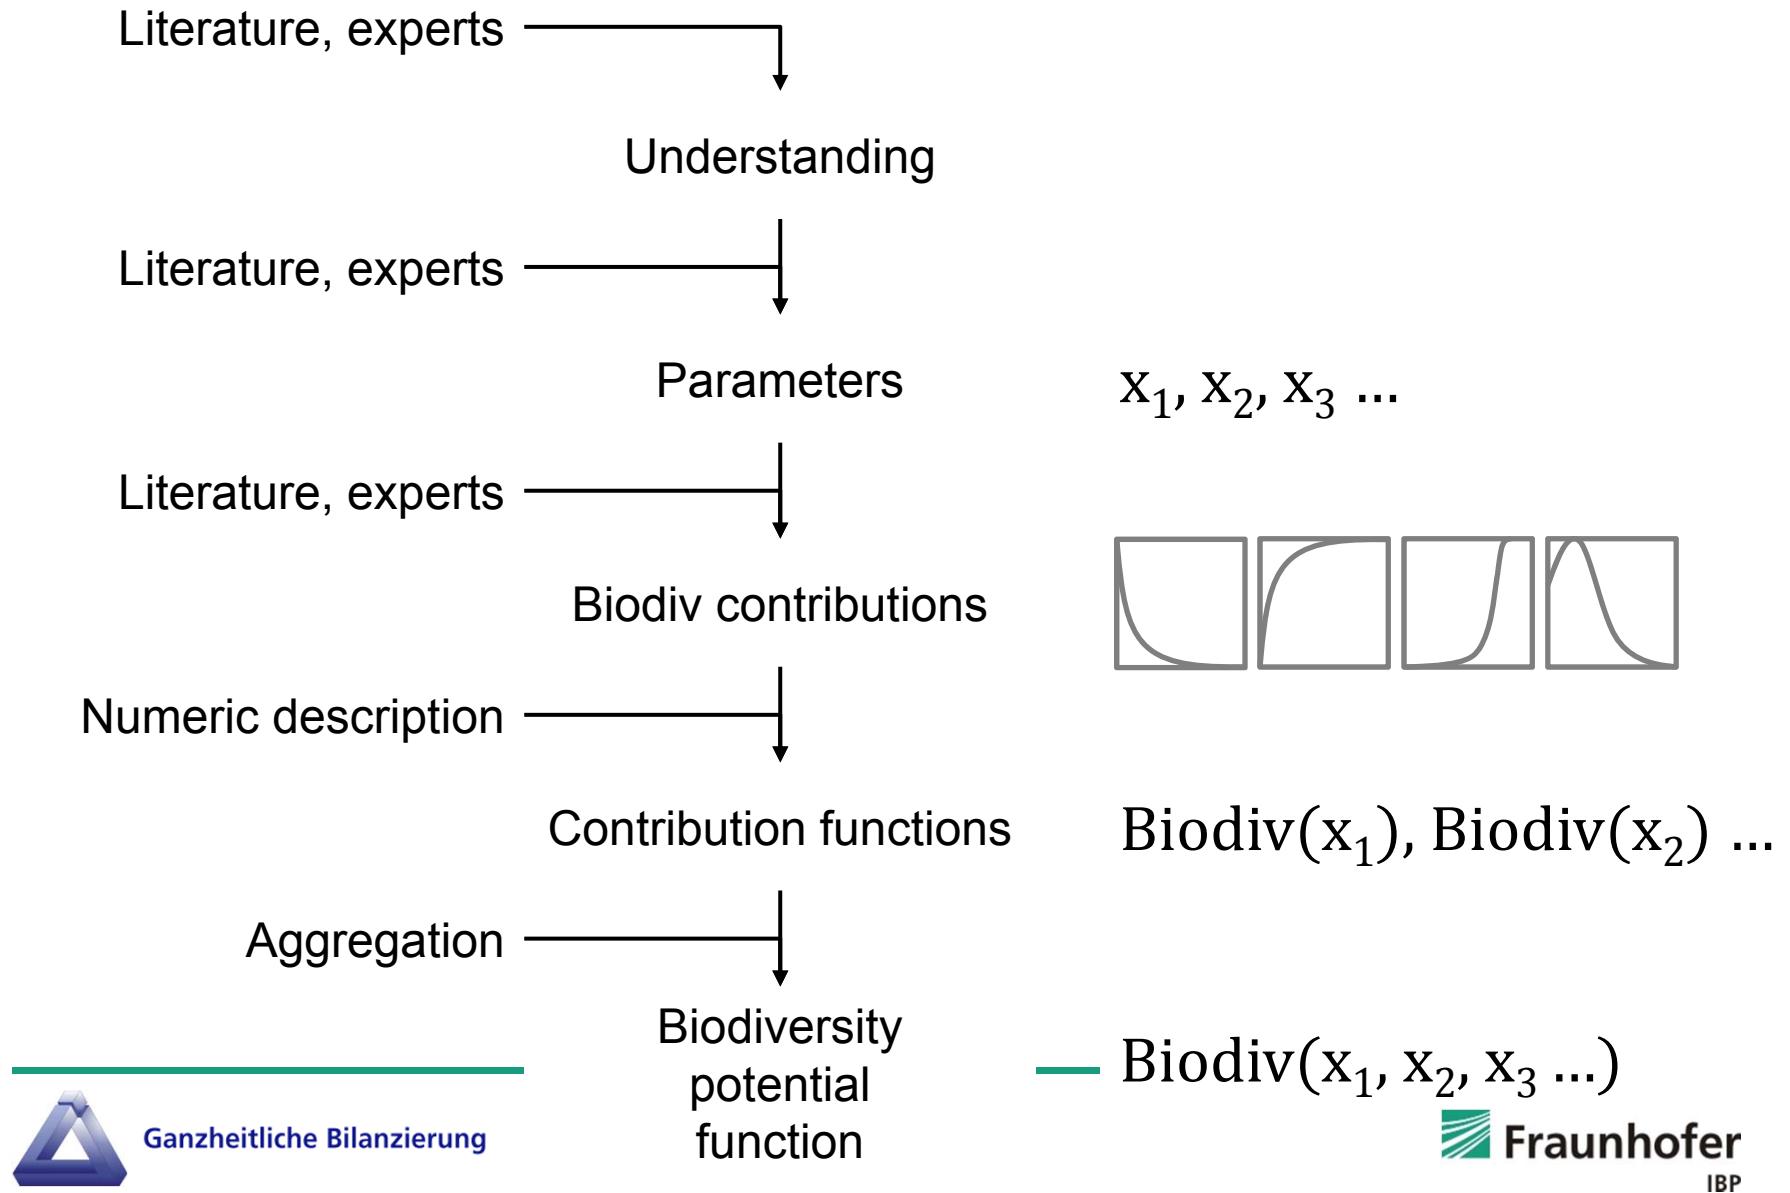

Repeat hierarchically for groups of parameters if necessary

Result: biodiversity potential function of a given ecoregion

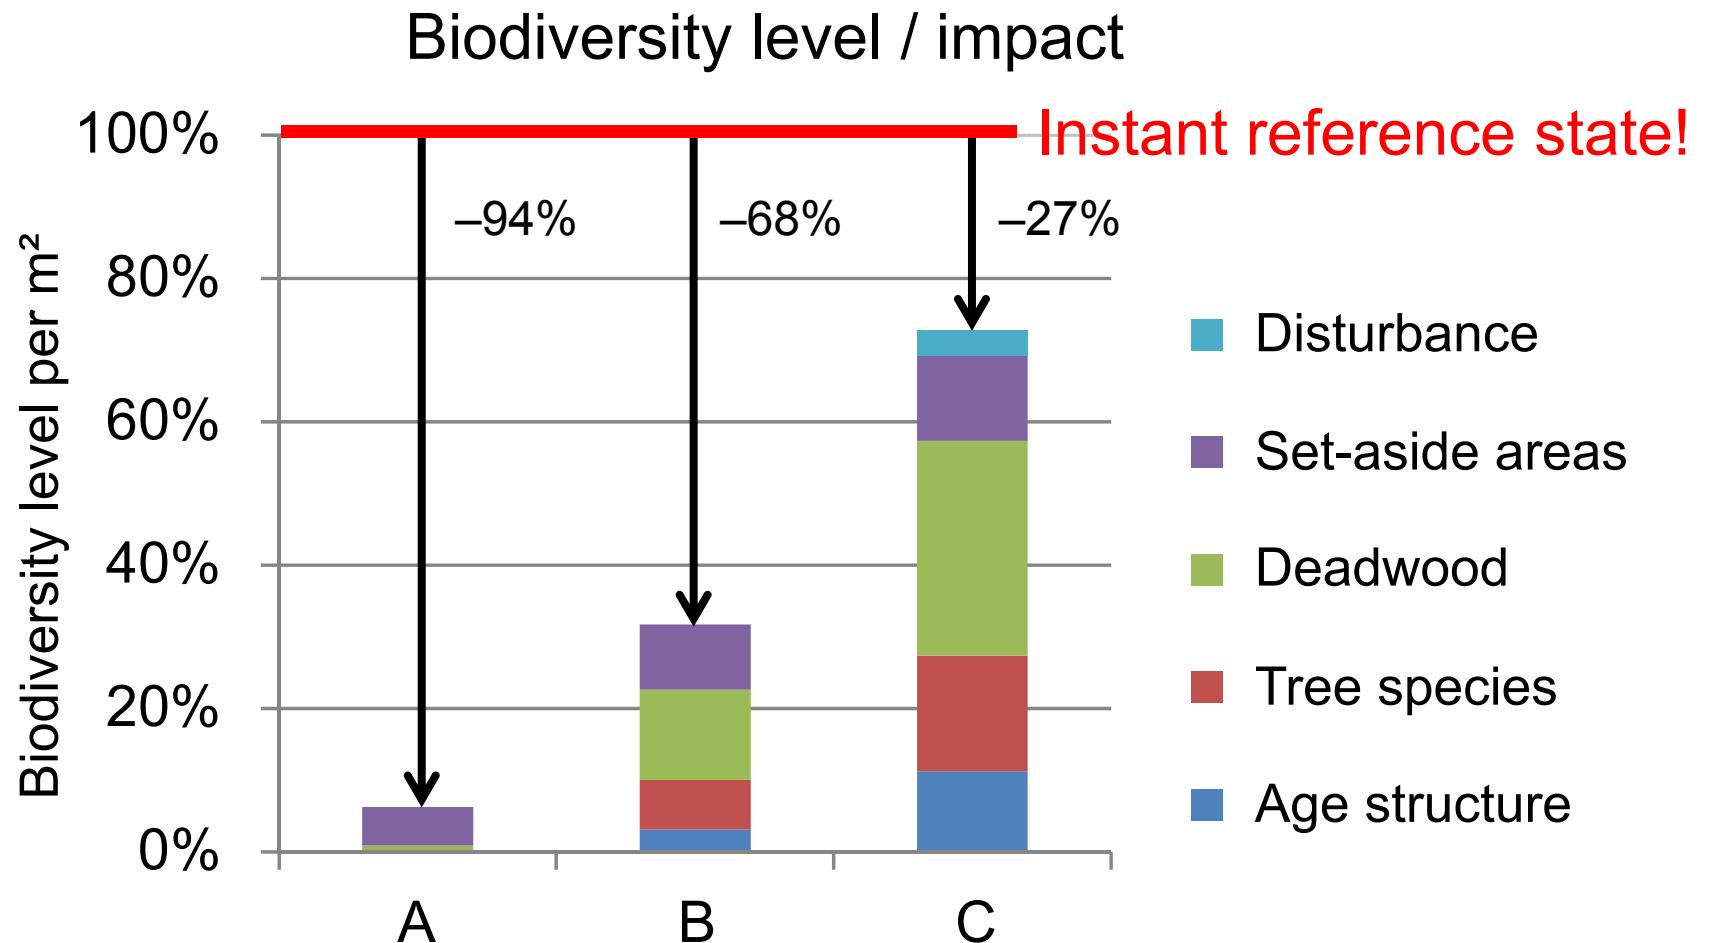

Ganzheitliche Bilanzierung

# Developing a biodiversity potential function

## Example results: forestry in Scandinavia

Ganzheitliche Bilanzierung

Fraunhofer  
IBP

# Conclusions, outlook, critique

## Biodiversity Impact Assessment

- Framework allows integration of various parameters,  
various relations between parameters,  
various aggregation methods
- Dissects abstract concept „biodiversity“ into parameters and contributions
- Relies on expert judgement, formulates algorithm for replication
- Compatible with overall UNEP-SETAC land use framework,  
possible integration with other approaches (e.g. foreground/background)
- Reference state obtained automatically with development of regionally specific  
biodiversity description

Critique, please!
